Executive Summary

Most recent collection

At 220.7 specimens per trap, the most recent trap collection (May 27, 2014) saw normal (medium) levels of mosquitoes for this time of year, with a concentration in the southeastern area of the county.

Forecast

With 70% confidence, we forecast that mosquito levels will remain at medium-low levels (the equivalent weekly rate of fewer than 320 mosquitoes per trap) throughout the week, falling slightly by June 16th to approximately 150 mosquitoes per trap.

Visual Overview

Time

As with previous years, the current mosquito population is at medium-low levels.

Space

Mosquito numbers were highest in the traps in the east (Hawthorne) and south (Micanopy) of the county.

Normality

The most recent collection was at levels equivalent to approximately the 73rd percentile of historical (2008-13) levels.

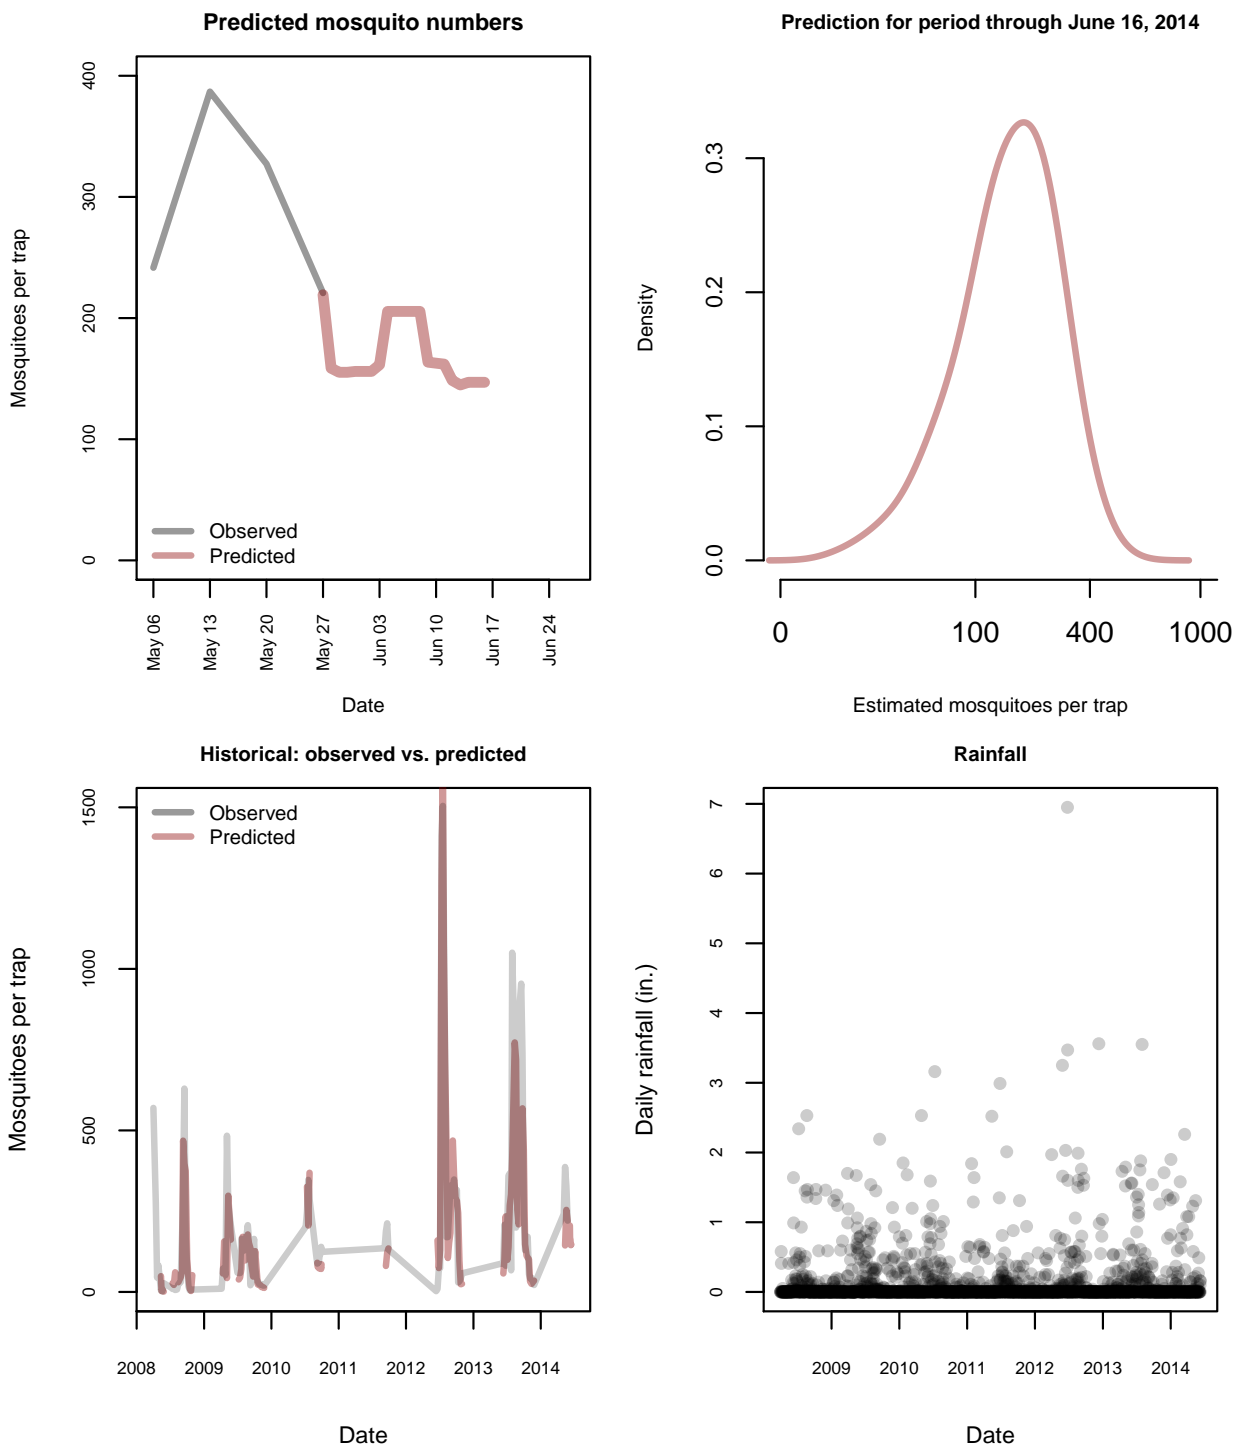

Disease Vectors

Of recently trapped mosquitoes, those species capable of carrying West Nile Virus are at high levels.

Forecast

We use recursive, quadratic linear regression modelling to forecast the average number of mosquitoes per trap up to 15 days in advance.¹

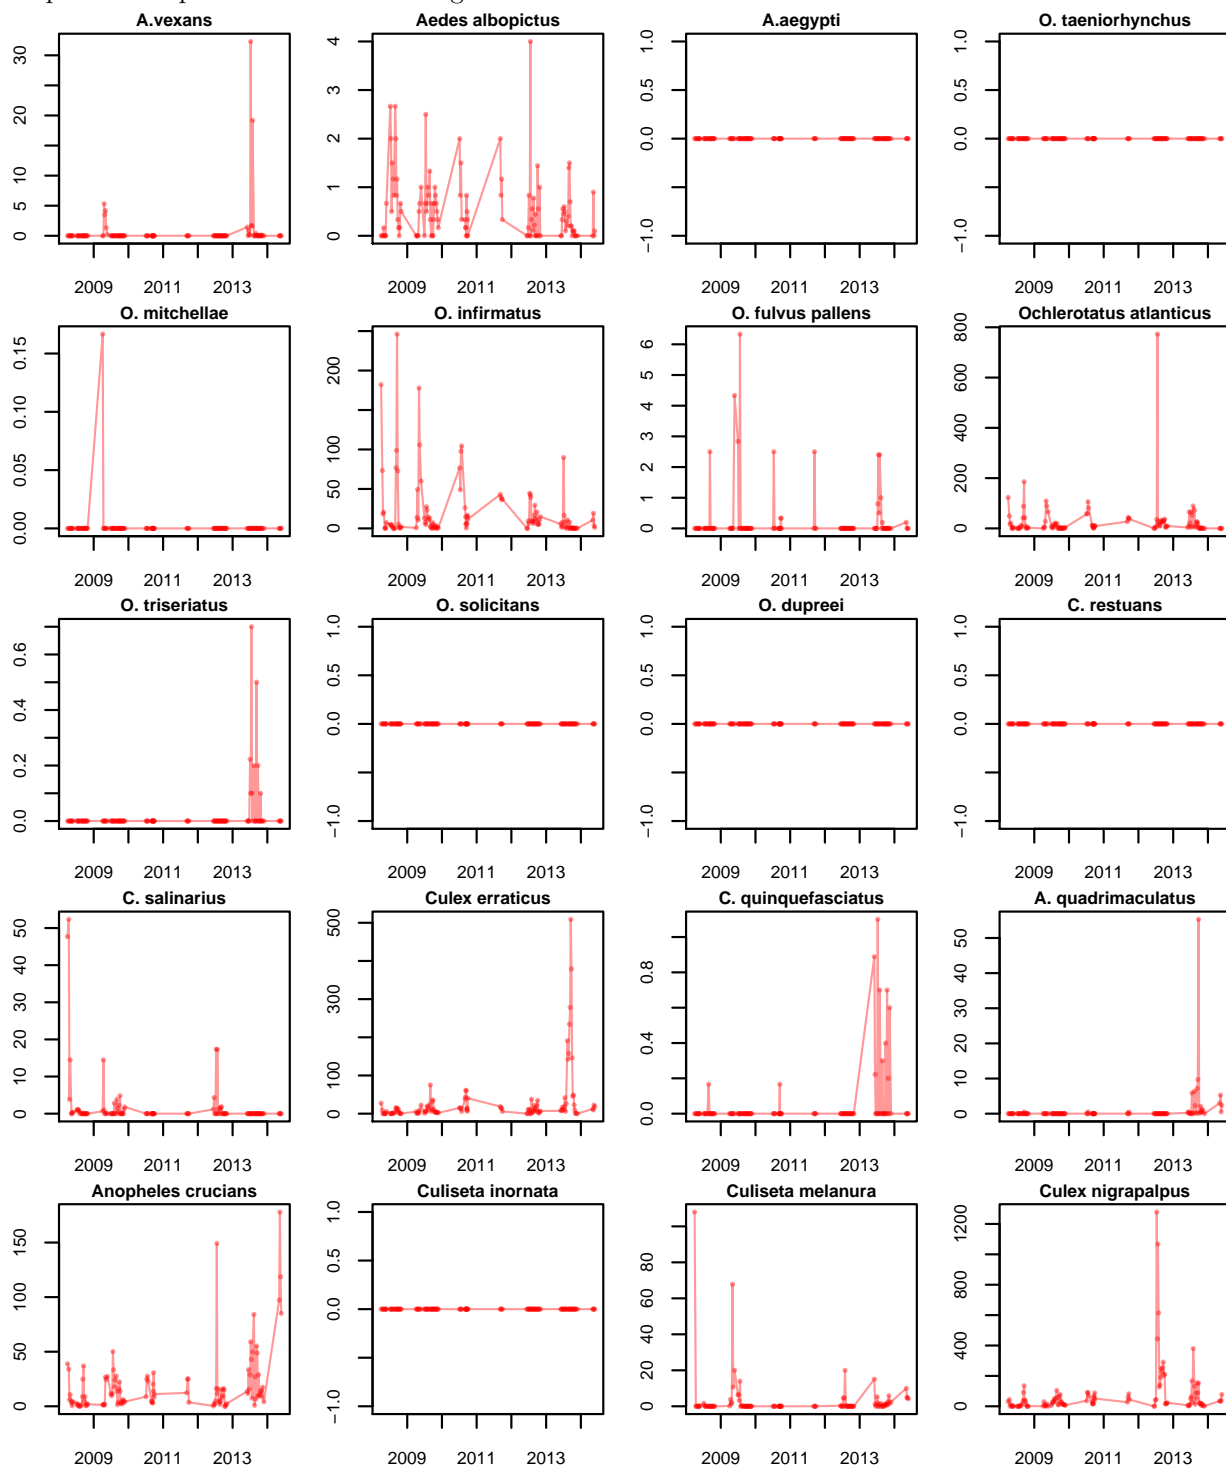

¹For the first report, our forecast only extends one week in advance, due to delays in modelling and obtaining data.

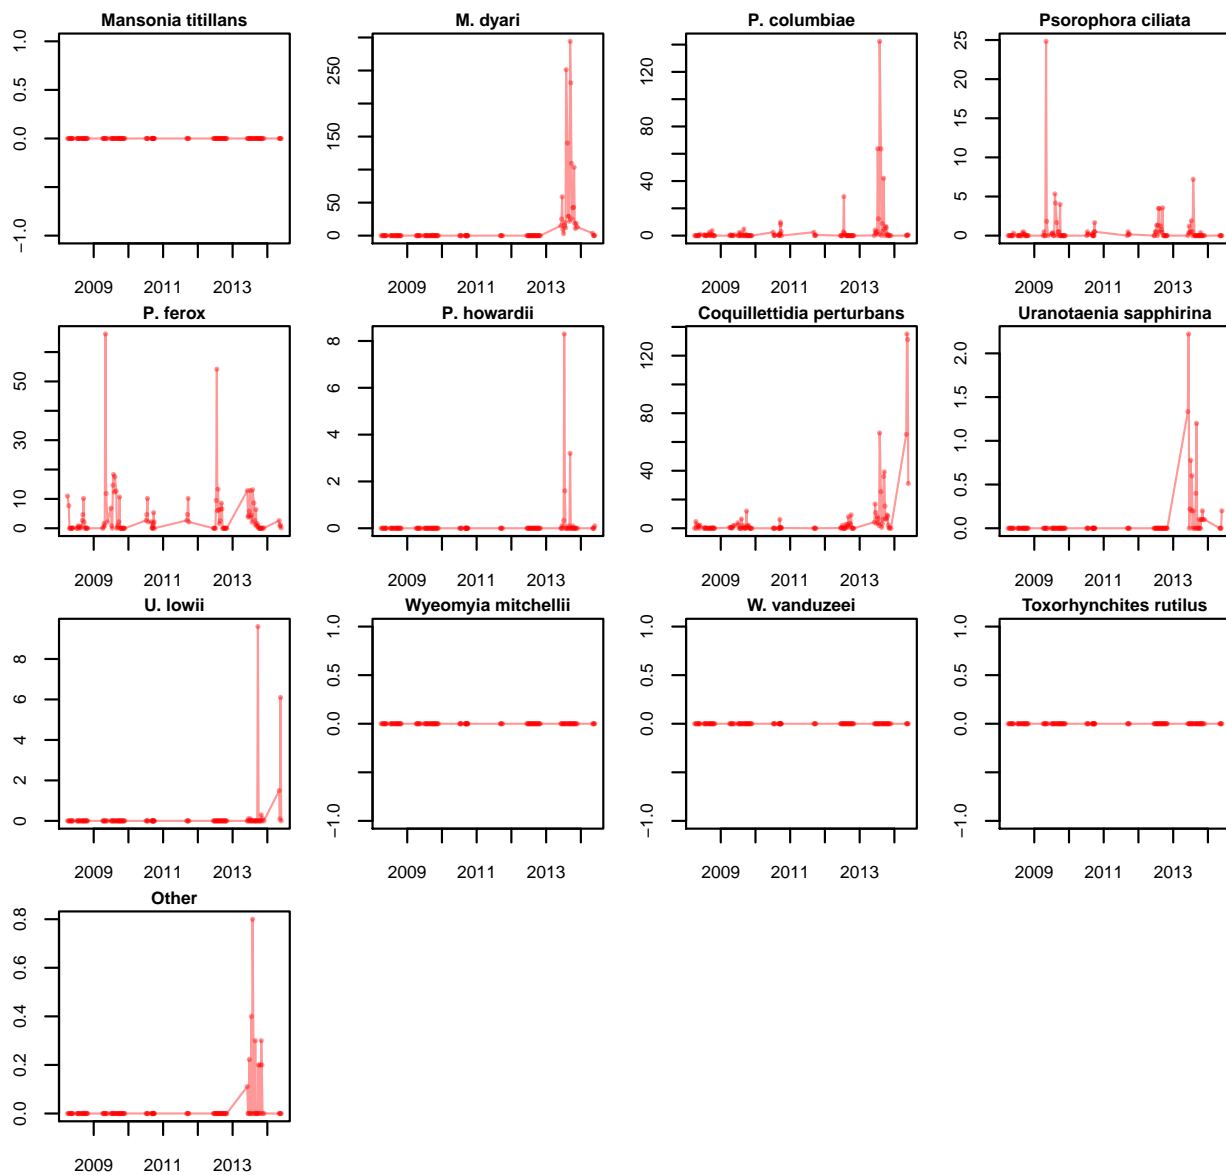

Disease Types By Location

Mosquito Types

No particular species shows abnormal growth in recent weeks.

Details of Predictive Model

Historically, the model has performed well, correctly predicting the late summer spikes in 2012 and 2013. Given the preference for accuracy at high numbers, the model intentionally includes outlying high observations, thereby weighting them.

Having simulated more than 65,000 unique models, our best fit equation (using the sum of least squares approach) was:

$$\hat{Y} = \beta_0 + \beta_1^2(5.6508) + \beta_2(0.5938)$$

where \hat{Y} is the estimated mean number of mosquitoes per trap, β_0 is set to 0, β_1 is the cumulative rainfall in the period 15 to 29 days prior to the date of prediction and β_2 is the mean number of mosquitoes per trap in the most recent prior trap collection.

Though an original model relied only on rainfall, incorporating the most recent trap prediction saw our R-squared improve from 0.52 to 0.82. This means that we can now explain over 80% of the variance in mosquito populations up to 15 days ahead of time.
